

CLAIMS

What is claimed is:

1. A method of debugging software comprising:

obtaining a software module;

5 obtaining a first input test vector;

obtaining a bug list;

generating a first output vector by applying said first input test vector to said software

module;

applying a comparison test to said first output vector to determine whether a bug

10 exists in said software module;

applying a module decomposition test to said software module when the result of said
comparison test is positive; and

appending said software module and said first input test vector to said bug list when
the result of said module decomposition test is negative.

15

2. The method of claim 1 wherein said comparison test comprises:

obtaining an optimal result vector;

comparing said first output vector to said optimal result vector; and

determining whether said first output vector is at variance with said optimal result

20 vector.

3. The method of claim 2 wherein the step of generating a bug list further
comprises:

obtaining a module decomposition list comprising two or more submodules of said software module when the result of said module decomposition test is positive; and iteratively processing said module decomposition list.

5 4. The method of claim 3 wherein the iterative processing step comprises:
obtaining a second input test vector such that the application of said second input test vector to said submodule will generate a second output test vector; and recursively processing said submodule and said second output test vector.

10 5. The method of claim 4 wherein the trimming step comprises:
obtaining said minimal module;
obtaining said first input test vector; and
applying a vector decomposition test to said first input test vector.

15 6. The method of claim 5 further comprising:
generating a third output vector by applying said first input test vector to said minimal module when the result of said vector decomposition test is negative;
applying said comparison test to said third output vector to determine whether said first input test vector recreates the bug; and
20 appending said input test vector to a test list when the result of said comparison test is positive.

7. The method of claim 6 further comprising:

obtaining a vector decomposition list comprising two or more subvectors of said first input test vector when the result of said vector decomposition test is positive; and iteratively processing each entry in said vector decomposition list by recursively applying said vector decomposition test to said subvectors.

5

8. The method of claim 7 in which said software module and said input test vector are obtained by iterating through the entries in said bug list.
